# 7. Linear equations

- QR factorization method
- factor and solve
- LU factorization

### QR factorization and matrix inverse

#### QR factorization of nonsingular matrix

every nonsingular  $A \in \mathbf{R}^{n \times n}$  has a QR factorization

$$A = QR$$

- $Q \in \mathbf{R}^{n \times n}$  is orthogonal  $(Q^T Q = Q Q^T = I)$
- $R \in \mathbb{R}^{n \times n}$  is upper triangular with positive diagonal elements

**Inverse from QR factorization:** the inverse  $A^{-1}$  can be written as

$$A^{-1} = (QR)^{-1} = R^{-1}Q^{-1} = R^{-1}Q^{T}$$

## Solving linear equations by QR factorization

**Algorithm:** to solve Ax = b with nonsingular  $A \in \mathbf{R}^{n \times n}$ ,

- 1. factor A as A = QR
- 2. compute  $y = Q^T b$
- 3. solve Rx = y by back substitution

Complexity:  $2n^3 + 3n^2 \approx 2n^3$  flops

- QR factorization:  $2n^3$
- matrix-vector multiplication:  $2n^2$
- back substitution:  $n^2$

## Multiple right-hand sides

consider k sets of linear equations with the same coefficient matrix A:

$$Ax_1 = b_1, Ax_2 = b_2, \dots, Ax_k = b_k$$

- equivalently, solve AX = B where B is  $n \times k$  matrix with columns  $b_1, \ldots, b_k$
- can be solved in  $2n^3 + 3kn^2$  flops if we reuse the factorization A = QR
- for  $k \ll n$ , cost is roughly equal to cost of solving one equation  $(2n^3)$

**Application:** to compute  $A^{-1}$ , solve the matrix equation AX = I

equivalent to n equations

$$Rx_1 = Q^T e_1, \qquad Rx_2 = Q^T e_2, \qquad \dots, \qquad Rx_n = Q^T e_n$$

( $x_i$  is column i of X and  $Q^T e_i$  is transpose of ith row of Q)

• complexity is  $2n^3 + n^3 = 3n^3$  (here the 2nd term  $n^3$  is not negligible)

### **Outline**

- QR factorization method
- factor and solve
- LU factorization

## Factor-solve approach

to solve Ax = b, first write A as a product of "simple" matrices

$$A = A_1 A_2 \cdots A_k$$

then solve  $(A_1A_2\cdots A_k)x=b$  by solving k equations

$$A_1z_1 = b$$
,  $A_2z_2 = z_1$ , ...,  $A_{k-1}z_{k-1} = z_{k-2}$ ,  $A_kx = z_{k-1}$ 

### **Examples**

- QR factorization: k = 2, A = QR
- LU factorization (this lecture)
- Cholesky factorization (later)

## Complexity of factor-solve method

$$\#flops = f + s$$

- f is complexity of factoring A as  $A = A_1 A_2 \cdots A_k$  (factorization step)
- s is complexity of solving the k equations for  $z_1, z_2, \ldots z_{k-1}, x$  (solve step)
- usually  $f \gg s$

**Example:** solving linear equations using the QR factorization

$$f = 2n^3, \qquad s = 3n^2$$

### **Outline**

- QR factorization method
- factor and solve
- LU factorization

### LU factorization

### LU factorization without pivoting

$$A = LU$$

- L unit lower triangular, U upper triangular
- does not always exist (even if *A* is nonsingular)

### **LU factorization** (with row pivoting)

$$A = PLU$$

- ullet P permutation matrix, L unit lower triangular, U upper triangular
- exists if and only if *A* is nonsingular (see later)

**Complexity**:  $(2/3)n^3$  if A is  $n \times n$ 

## Solving linear equations by LU factorization

**Algorithm:** to solve Ax = b with nonsingular A of size  $n \times n$ 

- 1. factor A as  $A = PLU((2/3)n^3$  flops)
- 2. solve (PLU)x = b in three steps
  - (a) permutation:  $z_1 = P^T b$  (0 flops)
  - (b) forward substitution: solve  $Lz_2 = z_1$  ( $n^2$  flops)
  - (c) back substitution: solve  $Ux = z_2$  ( $n^2$  flops)

**Complexity**:  $(2/3)n^3 + 2n^2 \approx (2/3)n^3$  flops

this is the standard method for solving Ax = b

## **Multiple right-hand sides**

two equations with the same matrix A (nonsingular and  $n \times n$ ):

$$Ax = b, \qquad A\tilde{x} = \tilde{b}$$

- factor A once
- forward/back substitution to get x
- forward/back substitution to get  $\tilde{x}$

complexity:  $(2/3)n^3 + 4n^2 \approx (2/3)n^3$ 

**Exercise**: propose an efficient method for solving

$$Ax = b, \qquad A^T \tilde{x} = \tilde{b}$$

### LU factorization and matrix inverse

suppose A is nonsingular and  $n \times n$ , with LU factorization

$$A = PLU$$

inverse from LU factorization

$$A^{-1} = (PLU)^{-1} = U^{-1}L^{-1}P^{T}$$

• gives interpretation of solve step: we evaluate

$$x = A^{-1}b = U^{-1}L^{-1}P^{T}b$$

in three steps

$$z_1 = P^T b,$$
  $z_2 = L^{-1} z_1,$   $x = U^{-1} z_2$ 

## **Computing the inverse**

solve AX = I column by column

• one LU factorization of  $A: 2n^3/3$  flops

• n solve steps:  $2n^3$  flops

• total:  $(8/3)n^3$  flops

slightly faster methods exist that exploit structure in right-hand side I

**Conclusion**: do not solve Ax = b by multiplying  $A^{-1}$  with b

### LU factorization without pivoting

$$\begin{bmatrix} A_{11} & A_{1,2:n} \\ A_{2:n,1} & A_{2:n,2:n} \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ L_{2:n,1} & L_{2:n,2:n} \end{bmatrix} \begin{bmatrix} U_{11} & U_{1,2:n} \\ 0 & U_{2:n,2:n} \end{bmatrix}$$
$$= \begin{bmatrix} U_{11} & U_{1,2:n} \\ U_{11}L_{2:n,1} & L_{2:n,1}U_{1,2:n} + L_{2:n,2:n}U_{2:n,2:n} \end{bmatrix}$$

#### **Recursive algorithm**

determine first row of U and first column of L

$$U_{11} = A_{11}, \qquad U_{1,2:n} = A_{1,2:n}, \qquad L_{2:n,1} = \frac{1}{A_{11}} A_{2:n,1}$$

• factor the  $(n-1) \times (n-1)$ -matrix  $A_{2:n,2:n} - L_{2:n,1}U_{1,2:n}$  as

$$A_{2:n,2:n} - L_{2:n,1}U_{1,2:n} = L_{2:n,2:n}U_{2:n,2:n}$$

this is an LU factorization (without pivoting) of size  $(n-1) \times (n-1)$ 

## **Example**

LU factorization (without pivoting) of

$$A = \left[ \begin{array}{ccc} 8 & 2 & 9 \\ 4 & 9 & 4 \\ 6 & 7 & 9 \end{array} \right]$$

write as A = LU with L unit lower triangular, U upper triangular

$$A = \begin{bmatrix} 8 & 2 & 9 \\ 4 & 9 & 4 \\ 6 & 7 & 9 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ L_{21} & 1 & 0 \\ L_{31} & L_{32} & 1 \end{bmatrix} \begin{bmatrix} U_{11} & U_{12} & U_{13} \\ 0 & U_{22} & U_{23} \\ 0 & 0 & U_{33} \end{bmatrix}$$

### **Example**

• first row of *U*, first column of *L*:

$$\begin{bmatrix} 8 & 2 & 9 \\ 4 & 9 & 4 \\ 6 & 7 & 9 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 1/2 & 1 & 0 \\ 3/4 & L_{32} & 1 \end{bmatrix} \begin{bmatrix} 8 & 2 & 9 \\ 0 & U_{22} & U_{23} \\ 0 & 0 & U_{33} \end{bmatrix}$$

• second row of *U*, second column of *L*:

$$\begin{bmatrix} 9 & 4 \\ 7 & 9 \end{bmatrix} - \begin{bmatrix} 1/2 \\ 3/4 \end{bmatrix} \begin{bmatrix} 2 & 9 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ L_{32} & 1 \end{bmatrix} \begin{bmatrix} U_{22} & U_{23} \\ 0 & U_{33} \end{bmatrix}$$
$$\begin{bmatrix} 8 & -1/2 \\ 11/2 & 9/4 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 11/16 & 1 \end{bmatrix} \begin{bmatrix} 8 & -1/2 \\ 0 & U_{33} \end{bmatrix}$$

• third row of U:  $U_{33} = 9/4 + 11/32 = 83/32$ 

#### **Conclusion**

$$A = \begin{bmatrix} 8 & 2 & 9 \\ 4 & 9 & 4 \\ 6 & 7 & 9 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 1/2 & 1 & 0 \\ 3/4 & 11/16 & 1 \end{bmatrix} \begin{bmatrix} 8 & 2 & 9 \\ 0 & 8 & -1/2 \\ 0 & 0 & 83/32 \end{bmatrix}$$

### Not every nonsingular A can be factored as A = LU

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 2 \\ 0 & 1 & -1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ L_{21} & 1 & 0 \\ L_{31} & L_{32} & 1 \end{bmatrix} \begin{bmatrix} U_{11} & U_{12} & U_{13} \\ 0 & U_{22} & U_{23} \\ 0 & 0 & U_{33} \end{bmatrix}$$

• first row of *U*, first column of *L*:

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 2 \\ 0 & 1 & -1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & L_{32} & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & U_{22} & U_{23} \\ 0 & 0 & U_{33} \end{bmatrix}$$

• second row of *U*, second column of *L*:

$$\begin{bmatrix} 0 & 2 \\ 1 & -1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ L_{32} & 1 \end{bmatrix} \begin{bmatrix} U_{22} & U_{23} \\ 0 & U_{33} \end{bmatrix}$$

$$U_{22} = 0$$
,  $U_{23} = 2$ ,  $L_{32} \cdot 0 = 1$ ?

## LU factorization (with row pivoting)

if A is  $n \times n$  and nonsingular, then it can be factored as

$$A = PLU$$

P is a permutation matrix, L is unit lower triangular, U is upper triangular

- not unique; there may be several possible choices for P, L, U
- interpretation: permute the rows of A and factor  $P^TA$  as  $P^TA = LU$
- also known as Gaussian elimination with partial pivoting (GEPP)
- complexity:  $(2/3)n^3$  flops

we skip the details of calculating P, L, U

## **Example**

$$\begin{bmatrix} 0 & 5 & 5 \\ 2 & 9 & 0 \\ 6 & 8 & 8 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 1/3 & 1 & 0 \\ 0 & 15/19 & 1 \end{bmatrix} \begin{bmatrix} 6 & 8 & 8 \\ 0 & 19/3 & -8/3 \\ 0 & 0 & 135/19 \end{bmatrix}$$

the factorization is not unique; the same matrix can be factored as

$$\begin{bmatrix} 0 & 5 & 5 \\ 2 & 9 & 0 \\ 6 & 8 & 8 \end{bmatrix} = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 3 & -19/5 & 1 \end{bmatrix} \begin{bmatrix} 2 & 9 & 0 \\ 0 & 5 & 5 \\ 0 & 0 & 27 \end{bmatrix}$$

## **Effect of rounding error**

$$\begin{bmatrix} 10^{-5} & 1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

solution:

$$x_1 = \frac{-1}{1 - 10^{-5}}, \qquad x_2 = \frac{1}{1 - 10^{-5}}$$

let us solve using LU factorization for the two possible permutations:

$$P = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{or} \quad P = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$$

we round intermediate results to four significant decimal digits

## First choice: P = I (no pivoting)

$$\begin{bmatrix} 10^{-5} & 1 \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 10^{5} & 1 \end{bmatrix} \begin{bmatrix} 10^{-5} & 1 \\ 0 & 1 - 10^{5} \end{bmatrix}$$

• L, U rounded to 4 significant decimal digits

$$L = \begin{bmatrix} 1 & 0 \\ 10^5 & 1 \end{bmatrix}, \qquad U = \begin{bmatrix} 10^{-5} & 1 \\ 0 & -10^5 \end{bmatrix}$$

forward substitution

$$\begin{bmatrix} 1 & 0 \\ 10^5 & 1 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \implies z_1 = 1, \quad z_2 = -10^5$$

back substitution

$$\begin{bmatrix} 10^{-5} & 1 \\ 0 & -10^5 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 1 \\ -10^5 \end{bmatrix} \implies x_1 = 0, \quad x_2 = 1$$

error in  $x_1$  is 100%

## Second choice: interchange rows

$$\begin{bmatrix} 1 & 1 \\ 10^{-5} & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 10^{-5} & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 0 & 1 - 10^{-5} \end{bmatrix}$$

• L, U rounded to 4 significant decimal digits

$$L = \begin{bmatrix} 1 & 0 \\ 10^{-5} & 1 \end{bmatrix}, \qquad U = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}$$

forward substitution

$$\begin{bmatrix} 1 & 0 \\ 10^{-5} & 1 \end{bmatrix} \begin{bmatrix} z_1 \\ z_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \implies z_1 = 0, \quad z_2 = 1$$

backward substitution

$$\begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix} \implies x_1 = -1, \quad x_2 = 1$$

error in  $x_1$ ,  $x_2$  is about  $10^{-5}$ 

### Conclusion: rounding error and LU factorization

- for some choices of P, small errors in the algorithm can cause very large errors in the solution
- this is called *numerical instability:* for the first choice of *P* in the example, the algorithm is unstable; for the second choice of *P*, it is stable
- from numerical analysis: there is a simple rule for selecting a good permutation (we skip the details, since we skipped the details of the factorization)

Linear equations 7.21

## **Sparse linear equations**

if A is sparse, it is usually factored as

$$A = P_1 L U P_2$$

 $P_1$  and  $P_2$  are permutation matrices

• interpretation: permute rows and columns of A and factor  $\tilde{A} = P_1^T A P_2^T$ 

$$\tilde{A} = LU$$

- choice of  $P_1$  and  $P_2$  greatly affects the sparsity of L and U: several heuristic methods exist for selecting good permutations
- in practice: #flops  $\ll (2/3)n^3$ ; exact value depends on n, number of nonzero elements, sparsity pattern

### **Conclusion**

different levels of detail in understanding how linear equation solvers work

#### **Highest level**

- $x = A \setminus b \cos(2/3)n^3$
- more efficient than x = inv(A) \* b

**Intermediate level:** factorization step A = PLU followed by solve step

**Lowest level:** details of factorization A = PLU

- for most applications, level 1 is sufficient
- in some situations (e.g., multiple right-hand sides) level 2 is useful
- level 3 is important for experts who write numerical libraries
